# Chapter 1

# Introduction

The R convey library estimates measures of poverty, inequality, and wellbeing. There are two other R libraries covering this subject, vardpoor and laeken, however, only convey integrates seamlessly with the R survey package.

convey is free and open-source software that runs inside the R environment for statistical computing. Anyone can review and propose changes to the source code for this software. Readers are welcome to propose changes to this book as well.

### 1.1 Installation

In order to work with the **convey** library, you will need to have R running on your machine. If you have never used R before, you will need to install that software before **convey** can be accessed. Check out FlowingData for a concise list of resources for new R users. Once you have R loaded on your machine, you can install..

• the latest released version from CRAN with

```
install.packages("convey")
```

• the latest development version from github with

```
devtools::install_github("djalmapessoa/convey")
```

### 1.2 Complex surveys and statistical inference

In this book, we demonstrate how to measure poverty and income concentration in a population based on microdata collected from a complex survey sample. Most surveys administered by government agencies or larger research organizations utilize a sampling design that violates the assumption of simple random sampling (SRS), including:

- 1. Different units selection probabilities;
- 2. Clustering of units:
- 3. Stratification of clusters:
- 4. Reweighting to compensate for missing values and other adjustments.

Therefore, basic unweighted R commands such as mean() or glm() will not properly account for the weighting nor the measures of uncertainty (such as the confidence intervals) present in the dataset. For some examples of publicly-available complex survey data sets, see http://asdfree.com.

Unlike other software, the R convey package does not require that the user specify these parameters throughout the analysis. So long as the svydesign object or svrepdesign object has been constructed properly at the outset of the analysis, the convey package will incorporate the survey design automatically and produce statistics and variances that take the complex sample into account.

### 1.3 Usage Examples

In the following example, we've loaded the data set eusilc from the R libraries vardpoor and laeken.

```
library(vardpoor)
data(eusilc)
```

Next, we create an object of class survey.design using the function svydesign of the library survey:

```
library(survey)
des_eusilc <- svydesign(ids = ~rb030, strata =~db040, weights = ~rb050, data = eusilc)</pre>
```

Right after the creation of the design object des\_eusilc, we should use the function convey\_prep that adds an attribute to the survey design which saves information on the design object based upon the whole sample, needed to work with subset designs.

```
library(convey)
des_eusilc <- convey_prep( des_eusilc )</pre>
```

To estimate the at-risk-of-poverty rate, we use the function svyarpt:

```
svyarpr(~eqIncome, design=des_eusilc)
```

```
arpr SE eqIncome 0.14444 0.0028
```

To estimate the at-risk-of-poverty rate across domains defined by the variable db040 we use:

```
svyby(~eqIncome, by = ~db040, design = des_eusilc, FUN = svyarpr, deff = FALSE)
```

```
db040 eqIncome
                 Burgenland 0.1953984 0.017202243

Vorarlberg
                 Vorarlberg 0.1653731 0.013754670
```

Using the same data set, we estimate the quintile share ratio:

```
# for the whole population
svyqsr(~eqIncome, design=des_eusilc, alpha= .20)
```

```
qsr SE
eqIncome 3.97 0.0426

# for domains
svyby(~eqIncome, by = ~db040, design = des_eusilc,
    FUN = svyqsr, alpha= .20, deff = FALSE)
```

```

```

These functions can be used as S3 methods for the classes survey.design and svyrep.design.

Let's create a design object of class svyrep.design and run the function convey\_prep on it:

```
des_eusilc_rep <- as.svrepdesign(des_eusilc, type = "bootstrap")</pre>
des_eusilc_rep <- convey_prep(des_eusilc_rep)</pre>
```

and then use the function svyarpr:

```
svyarpr(~eqIncome, design=des eusilc rep)
            arpr
                     SE
eqIncome 0.14444 0.0029
svyby(~eqIncome, by = ~db040, design = des_eusilc_rep, FUN = svyarpr, deff = FALSE)
                      db040 eqIncome se.eqIncome
Burgenland

                   Salzburg 0.1378734 0.010367539
Salzburg
Styria
                     Styria 0.1437464 0.007484813
Tyrol
                     Tyrol 0.1530819 0.009775361
Upper Austria Upper Austria 0.1088977 0.006278053
Vienna
                     Vienna 0.1723468 0.007363970
Vorarlberg
                 Vorarlberg 0.1653731 0.010067298
```

The functions of the library convey are called in a similar way to the functions in library survey.

It is also possible to deal with missing values by using the argument na.rm.

```
# survey.design using a variable with missings
svygini( ~ py010n , design = des_eusilc )
      gini SE
py010n NA NA
svygini( ~ py010n , design = des_eusilc , na.rm = TRUE )
          gini
                   SE
py010n 0.64606 0.0036
# svyrep.design using a variable with missings
svygini( ~ py010n , design = des_eusilc_rep )
      gini SE
py010n
       NA NA
svygini( ~ py010n , design = des_eusilc_rep , na.rm = TRUE )
```

djalmapessoa\_look, where do these references go on this page? (Berger and Skinner, 2003) and (Osier, 2009) and (Deville, 1999)

### 1.4 Underlying Calculations

djalmapessoa\_look, please describe the general purpose of linearization

In the convey library, there are some basic functions that produce the linearized variables needed to measure income concentration and poverty. For example, looking at the income variable in some complex survey dataset, the quantile of that income variable can be linearized by the function convey::svyiqalpha and the sum total below any quantile of the variable is linearized by the function convey::svyisq.

From the linearized variables of these basic estimates, it is possible by using rules of composition, valid for influence functions, to derive the influence function of more complex estimates. By definition the influence function is a Gateaux derivative and the rules rules of composition valid for Gateaux derivatives also hold for Influence Functions.

The following property of Gateaux derivatives was often used in the library convey. Let g be a differentiable function of m variables. Suppose we want to compute the influence function of the estimator  $g(T_1, T_2, \ldots, T_m)$ , knowing the Influence function of the estimators  $T_i$ ,  $i = 1, \ldots, m$ . Then the following holds:

$$I(g(T_1, T_2, \dots, T_m)) = \sum_{i=1}^m \frac{\partial g}{\partial T_i} I(T_i)$$

In the library convey this rule is implemented by the function contrastinf which uses the R function derive to compute the formal partial derivatives  $\frac{\partial g}{\partial T_i}$ .

For example, suppose we want to linearize the Relative median poverty gap(rmpg), defined as the difference between the at-risk-of-poverty threshold (arpt) and the median of incomes less than the arpt relative to the arprt:

$$rmpg = \frac{arpt - medpoor}{arpt}$$

where medpoor is the median of incomes less than arpt.

Suppose we know how to linearize arpt and medpoor, then by applying the function contrastinf with

$$g(T_1, T_2) = \frac{(T_1 - T_2)}{T_1}$$

we linearize the rmpg.

### 1.5 The Variance Estimator

djalmapessoa\_look please add references to this section

The variance of the estimator  $T(\hat{M})$  can approximated by:

$$Var\left[T(\hat{M})\right] \cong var\left[\sum_{s} w_i z_i\right]$$

The linearized variable z is given by the derivative of the functional:

$$z_k = \lim_{t \to 0} \frac{T(M + t\delta_k) - T(M)}{t} = IT_k(M)$$

where,  $\delta_k$  is the Dirac measure in k:  $\delta_k(i) = 1$  if and only if i = k.

This derivative is called Influence Function and was introduced in the area of Robust Statistics.

### 1.6 Influence Functions

Some measures of poverty and income concentration are defined by non-differentiable functions so that it is not possible to use Taylor linearization to estimate their variances. An alternative is to use **Influence functions** as described in (Deville, 1999) and (Osier, 2009). The convey library implements this methodology to work with survey.design objects and also with svyrep.design objects.

Some examples of these measures are:

- At-risk-of-poverty threshold:  $arpt = .60q_{.50}$  where  $q_{.50}$  is the income median;
- At-risk-of-poverty rate  $arpr = \frac{\sum_{U} 1(y_i \leq arpt)}{N}.100$
- Quintile share ratio

$$qsr = \frac{\sum_{U} 1(y_i > q_{.80})}{\sum_{U} 1(y_i \le q_{.20})}$$

• Gini coefficient  $1 + G = \frac{2\sum_{U}(r_i-1)y_i}{N\sum_{U}y_i}$  where  $r_i$  is the rank of  $y_i$ .

Note that it is not possible to use Taylor linearization for these measures because they depend on quantiles and the Gini is defined as a function of ranks. This could be done using the approach proposed by Deville (1999) based upon influence functions.

Let U be a population of size N and M be a measure that allocates mass one to the set composed by one unit, that is  $M(i) = M_i = 1$  if  $i \in U$  and M(i) = 0 if  $i \notin U$ 

Now, a population parameter  $\theta$  can be expressed as a functional of M  $\theta = T(M)$ 

Examples of such parameters are:

- Total:  $Y = \sum_{U} y_i = \sum_{U} y_i M_i = \int y dM = T(M)$
- Ratio of two totals:  $R = \frac{Y}{X} = \frac{\int y dM}{\int x dM} = T(M)$
- Cumulative distribution function:  $F(x) = \frac{\sum_{U} 1(y_i \le x)}{N} = \frac{\int 1(y \le x) dM}{\int dM} = T(M)$

To estimate these parameters from the sample, we replace the measure M by the estimated measure  $\hat{M}$  defined by:  $\hat{M}(i) = \hat{M}_i = w_i$  if  $i \in s$  and  $\hat{M}(i) = 0$  if  $i \notin s$ .

The estimators of the population parameters can then be expressed as functional of the measure  $\hat{M}$ .

- Total:  $\hat{Y} = T(\hat{M}) = \int y d\hat{M} = \sum_{s} w_i y_i$
- Ratio of totals:  $\hat{R} = T(\hat{M}) = \frac{\int y d\hat{M}}{\int x d\hat{M}} = \frac{\sum_s w_i y_i}{\sum_s w_i x_i}$
- Cumulative distribution function:  $\hat{F}(x) = T(\hat{M}) = \frac{\int 1(y \le x) d\hat{M}}{\int d\hat{M}} = \frac{\sum_s w_i 1(y_i \le x)}{\sum_s w_i}$

### 1.7 Influence Function Examples

• Total:

$$IT_k(M) = \lim_{t \to 0} \frac{T(M + t\delta_k) - T(M)}{t}$$

$$= \lim_{t \to 0} \frac{\int y \cdot d(M + t\delta_k) - \int y \cdot dM}{t}$$

$$= \lim_{t \to 0} \frac{\int y \cdot d(t\delta_k)}{t} = y_k$$

• Ratio of two totals:

$$IR_k(M) = I\left(\frac{U}{V}\right)_k(M) = \frac{V(M) \times IU_k(M) - U(M) \times IV_k(M)}{V(M)^2}$$
$$= \frac{Xy_k - Yx_k}{X^2} = \frac{1}{X}(y_k - Rx_k)$$

### 1.8 Examples of Linearization Using the Influence Function

• At-risk-of-poverty threshold:

$$arpt = 0.6 \times m$$

where m is the median income.

$$z_k = -\frac{0.6}{f(m)} \times \frac{1}{N} \times [I(y_k \le m - 0.5)]$$

• At-risk-of-poverty rate:

$$arpr = \frac{\sum_{U} I(y_i \le t)}{\sum_{U} w_i}.100$$

$$z_k = \frac{1}{N} [I(y_k \le t) - t] - \frac{0.6}{N} \times \frac{f(t)}{f(m)} [I(y_k \le m) - 0.5]$$

where:

N - population size;

t - at-risk-of-poverty threshold;

 $y_k$  - income of person k;

m - median income;

f - income density function;

## 1.9 Replication Designs

 $djalmapessoa\_look$ , please describe how the software works differently on svrepdesign objects – as compared to svydesign objects

### 1.10 Decomposition

Some inequality and multidimensional poverty measures can be decomposed. As of December 2016, the decomposition methods in convey are limited to group decomposition.

For instance, the generalized entropy index can be decomposed into between and within group components. This sheds light on a very simple question: of the overall inequality, how much can be explained by inequalities between groups and within groups? Since this measure is additive decomposable, one can get estimates of the coefficients, SEs and covariance between components. For a more practical approach, see (Lima, 2013).

The Alkire-Foster class of multidimensional poverty indices can be decomposed by dimension and groups. This shows how much each group (or dimension) contribute to the overall poverty.

This technique can help understand where and who is more affected by inequality and poverty, contributing to more specific policy and economic analysis.

# Chapter 2

# Poverty Indices

### 2.1 At Risk of Poverty Ratio (svyarpr)

For additional usage examples of svyarpr, type ?convey::svyarpr in the R console. here are the references

(Osier, 2009) and (Deville, 1999)

## 2.2 At Risk of Poverty Threshold (svyarpt)

For additional usage examples of swyarpt, type ?convey::swyarpt in the R console.

here are the references

(Osier, 2009) and (Deville, 1999)

## 2.3 Relative Median Income Ratio (svyrmir)

For additional usage examples of svyrmir, type ?convey::svyrmir in the R console.

here are the references

(Osier, 2009) and (Deville, 1999)

## 2.4 Relative Median Poverty Gap (svyrmpg)

For additional usage examples of svyrmpg, type ?convey::svyrmpg in the R console.

here are the references

(Osier, 2009) and (Deville, 1999)

# 2.5 Median Income Below the At Risk of Poverty Threshold (svy-poormed)

For additional usage examples of svypoormed, type ?convey::svypoormed in the R console.

here are the references

(Osier, 2009) and (Deville, 1999)

### 2.6 Foster-Greer-Thorbecke class (svyfgt)

(Foster et al., 1984) proposed a family of indicators to measure poverty. This class of FGT measures, can be defined as

$$p = \frac{1}{N} \sum_{k \in U} h(y_k, \theta),$$

where

$$h(y_k, \theta) = \left[\frac{(\theta - y_k)}{\theta}\right]^{\gamma} \delta \{y_k \le \theta\},$$

where:  $\theta$  is the poverty threshold;  $\delta$  the indicator function that assigns value 1 if the condition  $\{y_k \leq \theta\}$  is satisfied and 0 otherwise, and  $\gamma$  is a non-negative constant.

When  $\gamma = 0$ , p can be interpreted as the poverty headcount ratio, and for  $\gamma \ge 1$ , the weight of the income shortfall of the poor to a power  $\gamma$ , (Foster and all, 1984).

The poverty measure FGT is implemented in the library convey by the function svyfgt. The argument thresh type of this function defines the type of poverty threshold adopted. There are three possible choices:

- 1. abs fixed and given by the argument thresh value
- 2. relq a proportion of a quantile fixed by the argument proportion and the quantile is defined by the argument order.
- 3. relm a proportion of the mean fixed the argument proportion

The quantile and the mean involved in the definition of the threshold are estimated for the whole population. When  $\gamma = 0$  and  $\theta = .6*MED$  the measure is equal to the indicator arpr computed by the function svyarpr.

Next, we give some examples of the function svyfgt to estimate the values of the FGT poverty index.

Consider first the poverty threshold fixed ( $\gamma = 0$ ) in the value 10000. The headcount ratio (FGT0) is

fgt0 SE eqIncome 0.11444 0.0027

The poverty gap (FGT1) ( $\gamma = 1$ ) index for the poverty threshold fixed at the same value is

fgt1 SE eqIncome 0.032085 0.0011

To estimate the FGT0 with the poverty threshold fixed at 0.6\*MED we fix the argument type\_thresh="relq" and use the default values for percent and order:

```
svyfgt(~eqIncome, des_eusilc, g=0, type_thresh= "relq")

    fgt0    SE
eqIncome 0.14444 0.0028

that matches the estimate obtained by
svyarpr(~eqIncome, design=des_eusilc, .5, .6)

    arpr    SE
eqIncome 0.14444 0.0028

To estimate the poverty gap(FGT1) with the poverty threshold equal to 0.6 * MEAN we use:
svyfgt(~eqIncome, des_eusilc, g=1, type_thresh= "relm")

    fgt1    SE
eqIncome 0.051187 0.0011
```

### A replication example

In July 2006, (Jenkins, 2008) presented at the North American Stata Users' Group Meetings on the stata Atkinson Index command. The example below reproduces those statistics.

Load and prepare the same data set:

```
# load the convey package
library(convey)
# load the survey library
library(survey)
# load the foreign library
library(foreign)
# create a temporary file on the local disk
tf <- tempfile()</pre>
# store the location of the presentation file
presentation_zip <- "http://repec.org/nasug2006/nasug2006_jenkins.zip"</pre>
# download jenkins' presentation to the temporary file
download.file( presentation_zip , tf , mode = 'wb' )
# unzip the contents of the archive
presentation_files <- unzip( tf , exdir = tempdir() )</pre>
# load the institute for fiscal studies' 1981, 1985, and 1991 data.frame objects
x81 <- read.dta( grep( "ifs81" , presentation_files , value = TRUE ) )</pre>
x85 <- read.dta( grep( "ifs85" , presentation_files , value = TRUE ) )
x91 <- read.dta( grep( "ifs91" , presentation_files , value = TRUE ) )</pre>
# NOTE: we recommend using ?convey::svyarpt rather than this unweighted calculation #
# calculate 60% of the unweighted median income in 1981
```

```
unwtd_arpt81 <- quantile( x81$eybhc0 , 0.5 ) * .6</pre>
# calculate 60% of the unweighted median income in 1985
unwtd_arpt85 <- quantile( x85$eybhc0 , 0.5 ) * .6</pre>
# calculate 60% of the unweighted median income in 1991
unwtd_arpt91 <- quantile( x91$eybhc0 , 0.5 ) * .6</pre>
# stack each of these three years of data into a single data.frame
x <- rbind( x81 , x85 , x91 )
Replicate the author's survey design statement from stata code..

(Foster et al., 1984) and (Berger and Skinner, 2003)

# Chapter 3

# Inequality Measurement

Another problem faced by societies is inequality. Economic inequality can have several different meanings: income, education, resources, opportunities, wellbeing, etc. Usually, studies on economic inequality focus on income distribution.

Most inequality data comes from censuses and household surveys. Therefore, in order to produce reliable estimates from this samples, appropriate procedures are necessary.

This chapter presents brief presentations on inequality measures, also providing replication examples if possible. It starts with the Lorenz curve and inequality measures derived from it, then the concept of entropy and measures based on it are presented.

### 3.1 Lorenz Curve (svylorenz)

Though not an inequality measure in itself, the Lorenz curve is a classic instrument of distribution analysis. Basically, it is a function that associates a cumulative share of the population to the share of the total income it owns. In mathematical terms,

$$L(p) = \frac{\int_{-\infty}^{Q_p} y f(y) dy}{\int_{-\infty}^{+\infty} y f(y) dy}$$

where  $Q_p$  is the quantile p of the population.

The two extreme distributive cases are

- Perfect equality:
  - Every individual has the same income;
  - Every share of the population has the same share of the income;
  - Therefore, the reference curve is

$$L(p) = p \ \forall p \in [0, 1].$$

- Perfect inequality:
  - One individual concentrates all of society's income, while the other individuals have zero income;
  - Therefore, the reference curve is

$$L(p) = \begin{cases} 0, & \forall p < 1 \\ 1, & \text{if } p = 1. \end{cases}$$

In order to evaluate the degree of inequality in a society, the analyst looks at the distance between the real curve and those two reference curves.

The estimator of this function was derived by (Kovacevic and Binder, 1997):

$$L(p) = \frac{\sum_{i \in S} w_i \cdot y_i \cdot \delta\{y_i \le \widehat{Q}_p\}}{\widehat{Y}}, \ 0 \le p \le 1.$$

Yet, this formula is used to calculate specific points of the curve and their respective SEs. The formula to plot an approximation of the continuous empirical curve comes from (Lerman and Yitzhaki, 1989).

### A replication example

In October 2016, (Jann, 2016) released a pre-publication working paper to estimate lorenz and concentration curves using stata. The example below reproduces the statistics presented in his section 4.1.

```
# load the convey package
library(convey)

# load the survey library
library(survey)

# load the stata-style webuse library
library(webuse)

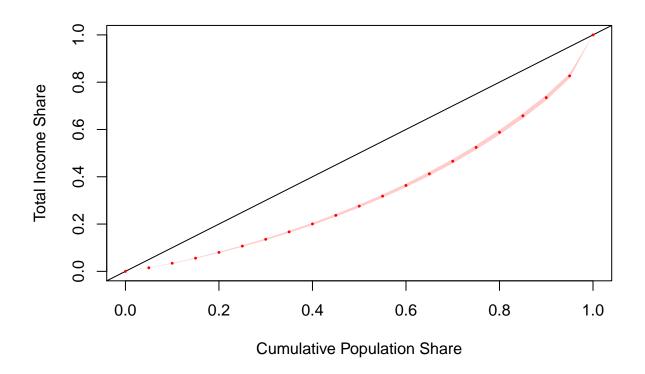

# load the NLSW 1988 data
webuse("nlsw88")

# coerce that `tbl_df` to a standard R `data.frame`
nlsw88 <- data.frame( nlsw88 )

# initiate a linearized survey design object
des_nlsw88 <- svydesign( ids = ~1 , data = nlsw88 )</pre>
```

```
## Warning in svydesign.default(ids = ~1, data = nlsw88): No weights or
## probabilities supplied, assuming equal probability
# immediately run the `convey_prep` function on the survey design
des_nlsw88 <- convey_prep(des_nlsw88)

# estimates lorenz curve
result.lin <- svylorenz( ~wage, des_nlsw88, quantiles = seq( 0, 1, .05 ), na.rm = T )</pre>
```

```
# note: most survey commands in R use Inf degrees of freedom by default
# stata generally uses the degrees of freedom of the survey design.
# therefore, while this extended syntax serves to prove a precise replication of stata
# it is generally not necessary.
section_four_one <-</pre>
    data.frame(
        estimate = coef( result.lin ) ,
        standard_error = SE( result.lin ) ,
        ci_lower_bound =
            coef( result.lin ) +
            SE( result.lin ) *
            qt( 0.025 , degf( subset( des_nlsw88 , !is.na( wage ) ) ) ) ,
        ci upper bound =
            coef( result.lin ) +
            SE( result.lin ) *
            qt( 0.975 , degf( subset( des_nlsw88 , !is.na( wage ) ) ) )
    )
knitr::kable(
  section_four_one , caption = 'Here is a nice table!',
  booktabs = TRUE
```

For additional usage examples of svylorenz, type ?convey::svylorenz in the R console.

Table 3.1: Here is a nice table!

## 3.2 Gini index (svygini)

The Gini index is an attempt to express the inequality presented in the Lorenz curve as a single number. In essence, it is twice the area between the equality curve and the real Lorenz curve. Put simply:

$$G = 2\left(\int_0^1 p dp - \int_0^1 L(p) dp\right)$$
$$\therefore G = 1 - 2\int_0^1 L(p) dp$$

where G = 0 in case of perfect equality and G = 1 in the case of perfect inequality.

The estimator proposed by (Osier, 2009) is defined as:

$$\widehat{G} = \frac{2\sum_{i \in S} w_i r_i y_i - \sum_{i \in S} w_i y_i}{\widehat{Y}}$$

The linearized formula of  $\widehat{G}$  is used to calculate the SE.

### A replication example

The R vardpoor package (Breidaks et al., 2016), created by researchers at the Central Statistical Bureau of Latvia, includes a gini coefficient calculation using the ultimate cluster method. The example below reproduces those statistics.

Load and prepare the same data set:

```
# load the convey package
library(convey)
# load the survey library
library(survey)
# load the vardpoor library
library(vardpoor)
# load the synthetic european union statistics on income & living conditions
data(eusilc)
# make all column names lowercase
names( eusilc ) <- tolower( names( eusilc ) )</pre>
# add a column with the row number
dati <- data.table(IDd = 1 : nrow(eusilc), eusilc)</pre>
# calculate the gini coefficient
# using the R vardpoor library
varpoord_gini_calculation <-</pre>
    varpoord(
        # analysis variable
        Y = "eqincome",
        # weights variable
        w_final = "rb050",
        # row number variable
        ID_level1 = "IDd",
        # strata variable
        H = "db040",
        N_h = NULL,
        # clustering variable
        PSU = "rb030",
        # data.table
        dataset = dati,
        # gini coefficient function
        type = "lingini"
    )
# all calculations produced by vardpoor::lingini
varpoord_gini_calculation$all_result
```

```

```

By default, the convey::svygini function comes close to the results of vardpoor::lingini. However, the measures of uncertainty do not line up, because library(vardpoor) defaults to the ultimate cluster method. This can be replicated with an alternative setup of the survey.design object. The ultimate cluster method is marginally less conservative, therefore, we do not recommend using it as the default.

```
# within each strata, sum up the weights
cluster_sums <- aggregate( eusilc$rb050 , list( eusilc$db040 ) , sum )
# name the within-strata sums of weights the `cluster_sum`</pre>
```

```
names( cluster_sums ) <- c( "db040" , "cluster_sum" )</pre>
# merge this column back onto the data.frame
eusilc <- merge( eusilc , cluster_sums )</pre>
# construct a survey.design
# with the fpc using the cluster sum
des_eusilc_ultimate_cluster <-
    svydesign(
        ids = ~rb030,
        strata = ~db040,
        weights = \sim rb050,
        data = eusilc ,
        fpc = ~ cluster_sum
    )
# again, immediately run the convey_prep function on the `survey.design`
des_eusilc_ultimate_cluster <- convey_prep( des_eusilc_ultimate_cluster )</pre>
# matches

For additional usage examples of svygini, type ?convey::svygini in the R console.

## 3.3 Amato index (svyamato)

The Amato index is also based on the Lorenz curve, but instead of focusing on the area of the curve, it focuses on its length. (Arnold, 2012) proposes a formula not directly based in the Lorenz curve, which (Barabesi et al., 2016) uses to present the following estimator:

$$\widehat{A} = \sum_{i \in S} w_i \left[ \frac{1}{\widehat{N}^2} + \frac{y_i^2}{\widehat{Y}^2} \right]^{\frac{1}{2}},$$

which also generates the linearized formula for SE estimation.

The minimum value A assumes is  $\sqrt{2}$  and the maximum is 2. In order to get a measure in the interval [0,1], the standardized Amato index  $\widetilde{A}$  can be defined as:

$$\widetilde{A} = \frac{A - \sqrt{2}}{2 - \sqrt{2}} \ .$$

For additional usage examples of svyamato, type ?convey::svyamato in the R console.

### 3.4 Zenga Index and Curve (svyzenga, svyzengacurve)

The Zenga index and its curve were proposed in (Zenga, 2007). As (Polisicchio and Porro, 2011) noticed, this curve derives directly from the Lorenz curve, and can be defined as:

$$Z(p) = 1 - \frac{L(p)}{p} \cdot \frac{1-p}{1-L(p)}.$$

In the convey library, an experimental estimator based on the Lorenz curve is used:

$$\widehat{Z(p)} = \frac{p\widehat{Y} - \widehat{\widetilde{Y}}(p)}{p\big[\widehat{Y} - \widehat{\widetilde{Y}}(p)\big]}.$$

In turn, the Zenga index derives from this curve and is defined as:

$$Z = \int_0^1 Z(p)dp.$$

However, its estimators were proposed by (Langel, 2012) and (Barabesi et al., 2016). In this library, the latter is used and is defined as:

$$\widehat{Z} = 1 - \sum_{i \in S} w_i \left[ \frac{(\widehat{N} - \widehat{H}_{y_i})(\widehat{Y} - \widehat{K}_{y_i})}{\widehat{N} \cdot \widehat{H}_{y_i} \cdot \widehat{K}_{y_i}} \right]$$

where  $\hat{N}$  is the population total,  $\hat{Y}$  is the total income,  $\hat{H}_{y_i}$  is the sum of incomes below or equal to  $y_i$  and  $\hat{N}_{y_i}$  is the sum of incomes greater or equal to  $y_i$ .

For additional usage examples of svyzenga or svyzengacurve, type ?convey::svyzenga or ?convey::svyzengacurve in the R console.

### 3.5 Entropy-based Measures

Entropy is a concept derived from information theory, meaning the expected amount of information given the occurrence of an event. Following (Shannon, 1948), given an event y with probability density function  $f(\cdot)$ , the information content given the occurrence of y can be defined as g(f(y)):  $= -\log f(y)$ . Therefore, the expected information or, put simply, the *entropy* is

$$H(f)$$
:  $= -E[\log f(y)] = -\int_{-\infty}^{\infty} f(y) \log f(y) dy$ 

Assuming a discrete distribution, with  $p_k$  as the probability of occurring event  $k \in K$ , the entropy formula takes the form:

$$H = -\sum_{k \in K} p_k \log p_k.$$

The main idea behind it is that the expected amount of information of an event is inversely proportional to the probability of its occurrence. In other words, the information derived from the observation of a rare event is higher than of the information of more probable events.

Using the intuition presented in (Cowell et al., 2009), substituting the density function by the income share of an individual  $s(q) = F^{-1}(q) / \int_0^1 F^{-1}(t) dt = y/\mu$ , the entropy function becomes the Theil inequality index

$$I_{Theil} = \int_0^\infty \frac{y}{\mu} \log\left(\frac{y}{\mu}\right) dF(y) = -H(s)$$

Therefore, the entropy-based inequality measure increases as a person's income y deviates from the mean  $\mu$ . This is the basic idea behind entropy-based inequality measures.

## 3.6 Generalized Entropy and Decomposition (svygei, svygeidec)

Using a generalization of the information function, now defined as  $g(f) = \frac{1}{\alpha - 1}[1 - f^{\alpha - 1}]$ , the  $\alpha$ -class entropy is

$$H_{\alpha}(f) = \frac{1}{\alpha - 1} \left[ 1 - \int_{-\infty}^{\infty} f(y)^{\alpha - 1} f(y) dy \right].$$

This relates to a class of inequality measures, the Generalized entropy indices, defined as:

$$GE_{\alpha} = \frac{1}{\alpha^2 - \alpha} \int_0^{\infty} \left[ \left( \frac{y}{\mu} \right)^{\alpha} - 1 \right] dF(x) = -\frac{-H_{\alpha}(s)}{\alpha}.$$

The parameter  $\alpha$  also has an economic interpretation: as  $\alpha$  increases, the influence of top incomes upon the index increases. In some cases, this measure takes special forms, such as mean log deviation and the aforementioned Theil index.

In order to estimate it, (Biewen and Jenkins, 2003) proposed the following:

$$GE_{\alpha} = \begin{cases} (\alpha^{2} - \alpha)^{-1} \left[ U_{0}^{\alpha - 1} U_{1}^{-\alpha} U_{\alpha} - 1 \right], & \text{if } \alpha \in \mathbb{R} \setminus \{0, 1\} \\ -T_{0} U_{0}^{-1} + \log(U_{1}/U_{0}), & \text{if } \alpha \to 0 \\ T_{1} U_{1}^{-1} - \log(U_{1}/U_{0}), & \text{if } \alpha \to 1 \end{cases}$$

where  $U_{\gamma} = \sum_{i \in S} w_i \cdot y_i^{\gamma}$  and  $T_{\gamma} = \sum_{i \in S} w_i \cdot y_i^{\gamma} \cdot \log y_i$ . since those are all functions of totals, the linearization of the indices are easily achieved using the theorems described in (Deville, 1999).

This class also has several desirable properties, such as additive decomposition. The additive decomposition allows to compare the effects of inequality within and between population groups on the population inequality. Put simply, an additive decomposable index allows for:

$$I_{Total} = I_{Retween} + I_{Within}$$

### A replication example

In July 2006, (Jenkins, 2008) presented at the North American Stata Users' Group Meetings on the stata Generalized Entropy Index command. The example below reproduces those statistics.

Load and prepare the same data set:

```
# load the convey package
library(convey)
# load the survey library
library(survey)
# load the foreign library
library(foreign)
# create a temporary file on the local disk
tf <- tempfile()</pre>
# store the location of the presentation file
presentation_zip <- "http://repec.org/nasug2006/nasug2006_jenkins.zip"</pre>
# download jenkins' presentation to the temporary file
download.file( presentation_zip , tf , mode = 'wb' )
# unzip the contents of the archive
presentation_files <- unzip( tf , exdir = tempdir() )</pre>
# load the institute for fiscal studies' 1981, 1985, and 1991 data.frame objects
x81 <- read.dta( grep( "ifs81" , presentation_files , value = TRUE ) )
x85 \leftarrow read.dta(grep("ifs85", presentation_files, value = TRUE))
x91 <- read.dta( grep( "ifs91" , presentation_files , value = TRUE ) )</pre>
# stack each of these three years of data into a single data.frame
x <- rbind( x81 , x85 , x91 )
```

Replicate the author's survey design statement from stata code..

```
. * account for clustering within HHs
. version 8: svyset [pweight = wgt], psu(hrn)
pweight is wgt
psu is hrn
construct an
.. into R code:
# initiate a linearized survey design object
y <- svydesign( ~ hrn , data = x , weights = ~ wgt )
# immediately run the `convey_prep` function on the survey design
z <- convey_prep( y )</pre>
```

Replicate the author's subset statement and each of his svygei results...

```
. svygei x if year == 1981
Warning: x has 20 values = 0. Not used in calculations
```

## 3.7 Rényi Divergence (svyrenyi)

Another measure used in areas like ecology, statistics and information theory is Rényi divergence measure. Using the formula defined in (Langel, 2012), the estimator can be defined as:

$$\widehat{R}_{\alpha} = \begin{cases} \frac{1}{\alpha - 1} \log \left[ \widehat{N}^{\alpha - 1} \sum_{i \in S} w_i \cdot \begin{pmatrix} y_k \\ \widehat{Y} \end{pmatrix} \right], & \text{if } \alpha \neq 1, \\ \sum_{i \in S} \frac{w_i y_i}{\widehat{Y}} \log \frac{\widehat{N} y_i}{\widehat{Y}}, & \text{if } \alpha = 1, \end{cases}$$

where  $\alpha$  is a parameter with a similar economic interpretation to that of the  $GE_{\alpha}$  index.

For additional usage examples of svyrenyi, type ?convey::svyrenyi in the R console.

## 3.8 J-Divergence and Decomposition (svyjdiv, svyjdivdec)

Proposed by (Rohde, 2016), the J-divergence measure can be seen as the sum of  $GE_0$  and  $GE_1$ , satisfying axioms that, individually, those two indices do not. Using  $U_{\gamma}$  and  $T_{\gamma}$  functions defined in ??, the estimator can be defined as:

$$\widehat{J} = \frac{1}{\widehat{N}} \sum_{i \in S} w_i \left( \frac{y_i - \widehat{\mu}}{\widehat{\mu}} \right) \log \left( \frac{y_i}{\widehat{\mu}} \right)$$

$$\therefore \widehat{J} = \frac{\widehat{T}_1}{\widehat{U}_1} - \frac{\widehat{T}_0}{\widehat{U}_0}$$

Since it is a sum of two additive decomposable measures, J itself is decomposable.

For additional usage examples of svyjdiv or svyjdivdec, type ?convey::svyjdiv or ?convey::svyjdivdec in the R console.

### 3.9 Atkinson index (svyatk)

Although the original formula was proposed in (Atkinson, 1970), the estimator used here comes from (Biewen and Jenkins, 2003):

$$\widehat{A}_{\epsilon} = \begin{cases} 1 - \widehat{U}_0^{-\epsilon/(1-\epsilon)} \widehat{U}_1^{-1} \widehat{U}_{1-\epsilon}^{1/(1-\epsilon)}, & \text{if } \epsilon \in \mathbb{R}_+ \setminus \{1\} \\ 1 - \widehat{U}_0 \widehat{U}_0^{-1} exp(\widehat{T}_0 \widehat{U}_0^{-1}), & \text{if } \epsilon \to 1 \end{cases}$$

The  $\epsilon$  is an inequality aversion parameter: as it approaches infinity, more weight is given to incomes in bottom of the distribution.

### A replication example

In July 2006, (Jenkins, 2008) presented at the North American Stata Users' Group Meetings on the stata Atkinson Index command. The example below reproduces those statistics.

Load and prepare the same data set:

```
# load the convey package
library(convey)
# load the survey library
library(survey)
# load the foreign library
library(foreign)
# create a temporary file on the local disk
tf <- tempfile()</pre>
# store the location of the presentation file
presentation_zip <- "http://repec.org/nasug2006/nasug2006_jenkins.zip"</pre>
# download jenkins' presentation to the temporary file
download.file( presentation_zip , tf , mode = 'wb' )
# unzip the contents of the archive
presentation_files <- unzip( tf , exdir = tempdir() )</pre>
# load the institute for fiscal studies' 1981, 1985, and 1991 data.frame objects
x81 <- read.dta( grep( "ifs81" , presentation_files , value = TRUE ) )
```

```
x85 <- read.dta( grep( "ifs85" , presentation_files , value = TRUE ) )</pre>
x91 <- read.dta( grep( "ifs91" , presentation_files , value = TRUE ) )</pre>
# stack each of these three years of data into a single data.frame
x <- rbind( x81 , x85 , x91 )

# Wellbeing Measures

djalmapessoa\_look do any of the other functions need to be moved to this wellbeing chapter?

### 4.1 The Gender Pay Gap (svygpg)

For additional usage examples of svygpg, type ?convey::svygpg in the R console. here are the references (Osier, 2009) and (Deville, 1999)

### 4.2 Quintile Share Ratio (svyqsr)

For additional usage examples of svyqsr, type ?convey::svyqsr in the R console. here are the references (Osier, 2009) and (Deville, 1999)

### Chapter 5

### Multidimensional Indices

Inequality and poverty can be seen as multidimensional concepts, combining several livelihood characteristics. Usual approaches take into account income, housing, sanitation, etc.

In order to transform these different measures from into meaningful numbers, economic theory builds on the idea of utility functions. Utility is a measure of well-being, assigning a "well-being score" to a vector of characteristics. Depending on the utility function, the analyst may allow for substitutions among characteristics: for instance, someone with a slightly lower income, but with access to sanitation, can have a higher wellbeing than someone with a higher income, but without access to sanitation. This depends on the set of weights given to the set of attributes.

Most measures below follow from this kind of two-step procedure: (1) estimating individual scores from an individual's set of characteristics; then (2) aggregating those individual scores into a single measure for the population.

The following section will present a measure of multidimensional poverty and a measure of multidimensional inequality, describing the main aspects of the theory and estimation procedures of each.

#### 5.1 Alkire-Foster Class and Decomposition (svyafc, svyafcdec)

This class of measures are defined in (Alkire and Foster, 2011), using what is called the "dual cutoff" approach. This method applies a cutoffs to define dimensional deprivations and another cutoff for multidimensional deprivation.

To analyze a population of n individuals across d achievement dimensions, the first step of the method is applying a FGT-like transformation to each dimension, defined as

$$g_{ij}^{\alpha} = \left(\frac{z_j - x_{ij}}{z_j}\right)^{\alpha}$$

where i is an observation index, j is a dimension index and  $\alpha$  is an exponent weighting the deprivation intensity. If  $\alpha=0$ , then  $g_{ij}^0$  becomes a binary variable, assuming value 1 if person i is deprived in dimension j and 0 otherwise. The  $n\times d$  matrix  $G^{\alpha}$  will be referred to as deprivation matrix.

Each dimension receives a weight  $w_j$ , so that the weighted sum of multidimensional deprivation is the matrix multiplication of  $G^{\alpha}$  by the  $j \times 1$  vector  $W = [w_j]$ . The  $n \times 1$  vector  $C^{\alpha} = [c_i^{\alpha}]$  is the weighted sum of dimensional deprivation scores, i.e.,

$$c_i^{\alpha} = \sum_{j \in d} w_j g_{ij}^{\alpha}$$

The second cutoff is defining those considered to be multidimensionally poor. Assuming that  $\sum_{j \in d} w_j = 1$ , the multidimensional cutoff k belongs to the interval (0,1]. If  $c_i^0 \ge k$ , then this person is considered multidimensionally poor. The censored vector of deprivation sums  $C^{\alpha}(k)$  is defined as

$$C^{\alpha}(k) = \left[ c_{ij}^{\alpha} \cdot \delta \left( c_{ij}^{0} \geqslant k \right) \right],$$

where  $\delta(A)$  is an indicator function, taking value 1 if condition A is true and 0 otherwise. If  $k \ge \min w_j$ , this is called the "union approach", where a person is considered poor if she is poor in at least one dimension. On the other extreme, the "intersection approach" happens when k = 1, meaning that a person is considered poor if she is poor in all dimensions.

The average of vector  $C^0(k)$  returns the multidimensional headcount ratio. For the multidimensional FGT class, a general measure can be defined as

$$M^{\alpha} = \frac{1}{n} \sum_{i \in n} \sum_{j \in d} w_j g_{ij}^{\alpha}(k), \ \alpha \ge 0,$$

where  $g_{ij}^{\alpha}(k) = g_{ij}^{\alpha} \cdot \delta(c_i^0 \geqslant k)$ .

For inferential purposes, since this variable is actually the average of scores  $\sum_{j \in d} w_j g_{ij}^{\alpha}(k)$ , the linearization is straightforward.

#### 5.1.1 Dimensional and group decomposition

The overall Alkire-Foster index is both dimensional and subgroup decomposable. This way, it is possible to analyze how much each dimension or group contribute to the general result.

The overall poverty measure can be seen as the weighted sum of each group poverty measure, as in the formula below:

$$M^{\alpha} = \sum_{l \in L} \frac{n_l}{n} M_l^{\alpha}$$

where l is one of L groups.

Also, the overall poverty index can be expressed across dimensions as

$$M^{\alpha} = \sum_{j \in d} w_j \left[ \frac{1}{n} \sum_{i \in n} g_{ij}^{\alpha}(k) \right].$$

Since those functions are linear combinations of ratios and totals, it is also possible to calculate standard errors for such measures.

#### A replication example

In November 2015, Christopher Jindra presented at the Oxford Poverty and Human Development Initiative on the Alkire-Foster multidimensional poverty measure. His presentation can be viewed here. The example below reproduces those statistics.

Load and prepare the same data set:

```
# load the convey package
library(convey)
# load the survey library
library(survey)
# load the stata-style webuse library
library(webuse)
# load the same microdata set used by Jindra in his presentation
webuse("nlsw88")
# coerce that `tbl_df` to a standard R `data.frame`
nlsw88 <- data.frame( nlsw88 )</pre>
# create a `collgrad` column
nlsw88$collgrad <-
    factor(
        as.numeric( nlsw88$collgrad ) ,
        label = c( 'not college grad' , 'college grad' ) ,
        ordered = TRUE
      )
# initiate a linearized survey design object
des_nlsw88 <- svydesign( ids = ~1 , data = nlsw88 )</pre>
# immediately run the `convey_prep` function on the survey design
des_nlsw88 <- convey_prep(des_nlsw88)</pre>

For additional usage examples of svyafc or svyafcdec, type ?convey::svyafc or ?convey::svyafcdec in the R console.

(Alkire and Foster, 2011) and (Sabina Alkire and Ballon, 2015) and (Pacifico and Poge, 2016)

#### 5.2 Bourguignon (1999) inequality class (svybmi)

For additional usage examples of svybmi, type ?convey::svybmi in the R console.

(Bourguignon, 1999) and (Ana Lugo, 2007)
